20. ABSTRACT (Continue on reverse side if necessary and identify by block number) This report summarizes energy requirements for small wastewater treatment systems (0.05 - 5 million gallons per day) applicable to military installations. It compares various treatment combinations, and presents the energy requirements for the most viable alternatives in tabular form. It also presents energy requirements for various components of wastewater treatment systems in a format making it convenient to calculate the energy requirements for many combinations of the components. In addition, it summarizes briefly energy

estimates made by others. The report compares typical combinations of unit operations and processes used to produce various quality effluents on the basis of energy consumption. It concludes that land application systems are the most energy-efficient wastewater treatment systems and that they are capable of producing an equivalent or higher quality effluent than any other treatment system.

## PREFACE

This report was prepared by E. Joe Middlebrooks and Charlotte H. Middlebrooks, both of Middlebrooks and Associates, Logan Utah.

The study was performed for the U.S. Army Cold Regions Research and Engineering Laboratory (USA CRREL) and was funded under DA Project 4A762720A896, Environmental Quality for Construction and Operation of Military Facilities; Task 02, Pollution Abatement Systems; Work Unit 004, Wastewater Treatment Techniques in Cold Regions.

The final scope of study was defined by Sherwood C. Reed of CRREL. He served as technical monitor during the course of the study and his efforts in this regard contributed significantly to the successful completion of this report.

Technical review of this report was performed by Sherwood C. Reed, Robert S. Sletten, C. James Martel, and Edward F. Lobacz of CRREL.

Permission to reproduce drawings, tables, promotional and instructional materials by the following firms is greatly appreciated.

16	Energy requirements for components of rapid infiltration land treatment systems located in the intermountain of the USA . . . . .	32
17	Energy requirements for components of overland flow land treatment systems located in the intermountain area of the USA . . . . .	33
18	Energy requirements for components of a facultative lagoon-intermittent sand filter system located in the intermountain area of the USA . . . . .	34
19	Energy requirements for components of an advanced wastewater treatment system processing secondary effluent located in the intermountain area of the USA . . . . .	35
20	Energy requirements for components frequently appended to secondary wastewater treatment plants . . . . .	36
21	Expected effluent quality and total energy requirements for various sizes and types of wastewater treatment plants located in the intermountain area of the USA . . . . .	38
22	Total annual energy for typical 1 mgd system (electrical plus fuel, expressed as 1000 kwh/yr) . . . . .	42

## SUMMARY

With increasing energy costs, energy consumption is assuming a greater proportion of the annual cost of operating wastewater treatment facilities of all sizes, and because of this trend, it is likely that energy costs will become the predominant factor in the selection of cost-effective small-flow wastewater treatment systems.

Where suitable land and groundwater conditions exist, a facultative pond followed by rapid infiltration is the most energy-efficient system described in this report. Where surface discharge is necessary and impermeable soils exist, a facultative pond followed by overland flow is the second most energy-efficient system described. Facultative ponds, followed by slow or intermittent sand filters, are the third most energy-efficient systems discussed, and are not limited by local soil or groundwater conditions.

## INTRODUCTION

### General

The concern for energy use at wastewater treatment facilities has developed well after many of the plans were made for the management of water pollution in the United States. This is true in military as well as in civilian installations. With changing standards and technology, information on energy requirements for small (0.05 to 5 mgd) wastewater treatment systems is needed to avoid future errors and to provide information to assist in designing and planning. Several estimates have been made for large systems, usually in the range of 5 to 100 mgd, but because hundreds of small systems are being used by military installations, it is imperative that information be gathered on energy requirements for wastewater treatment for small systems.

This report summarizes the energy requirements for all viable alternatives presently available to military installations for the treatment of small flow rates (0.05 - 5 mgd) of wastewater. It compares various treatment combinations, and presents in tabular form the energy requirements for the most viable alternatives. The data can be combined to produce an estimate of the energy requirements for all currently available unit operations and processes.

### Other Studies

Only one comprehensive study of the energy requirements associated with wastewater treatment has been performed. Wesner et al. (1978) presented a detailed analysis of energy requirements by unit operations and unit processes employed in wastewater treatment. The results of this study were presented in graphical form with accompanying tables outlining the design considerations employed in developing the graphs. Energy requirements were presented in terms of the design flow rate of the treatment system in most cases, but when a wide choice of loading rates was applicable, the graphs were presented in terms of surface area or the flow rate applied to the component of the system. Portions of the Wesner et al. (1978) results are presented in detail in Appendix A in this report.

Culp (1978) has presented an analysis of alternatives for future wastewater treatment at South Tahoe, California. This illustrates the increasing sensitivity of energy costs. When the original advanced wastewater treatment system was constructed in the late 1960's, energy was not costly and was not usually a significant factor in concept selection and design. Table 1 illustrates the energy required for alternatives compared with the original design. It is anticipated that the final product

Table 1. Energy requirements 7.5 mgd, Lake Tahoe Wastewater Treatment system (Culp and Culp, 1971; Culp, 1978).

Alternative	Total energy <sup>a</sup> (electricity and fuel expressed as equivalent 1000 kwh/yr)
Original system complete secondary treatment, AWT system, effluent export to Indian Creek Reservoir	64,500
1978 Alternatives	
Continue secondary, nitrification, effluent export to Indian Creek Reservoir	39,400
Continue secondary, nitrogen removal (ion exchange) effluent export to I.C.R.	40,244
Continue secondary on site, flood irrigation land treatment in Carson River Basin	25,000

<sup>a</sup>Does not include secondary energy requirements for chemical manufacture.

from the flood irrigation land treatment alternative will be at least equal in quality to the original design effluent.

Energy requirements for four wastewater treatment systems, including sludge processing, that are capable of achieving secondary effluent quality and complete sludge treatment and disposal were presented by Wesner and Burris (1978). Estimated energy requirements were presented for 1) trickling filter with anaerobic digestion, 2) activated sludge with anaerobic digestion, 3) activated sludge with sludge incineration, and 4) independent physical-chemical treatment with sludge incineration using 5 and 30 mgd capacities. A comparison of energy requirements for the four systems treating 30 mgd is shown in Figure 1. The potential for solar energy as a method of heating the digester and control building was discussed. Heat recovery from sewage effluents using heat pumps to heat digesters and buildings was considered.

Zarnett (1976, 1977, and undated) has examined the energy requirements for water and wastewater treatment plants and has presented the requirements by unit operations employed. The results were presented by unit operation to make it convenient to assess any treatment system on the basis of total energy consumption. By combining various flow configurations, a system capable of producing a given effluent quality can be assembled and the energy requirements compared. Zarnett cautions

Figure 1. Energy requirements for 30 mgd secondary treatment plants (Wesner and Burris, 1978).  
Courtesy of Journal Water Pollution Control Federation, Washington, D.C.

that the data were presented for comparative purposes and should not be used as absolute values.

Energy requirements for various types of wastewater treatment plants were presented by Hagan and Roberts (1976). In addition to the discussion of conventional secondary and tertiary treatment systems, land treatment systems were considered. Tradeoffs between pollutants removed from wastewater and pollutants added to the environment by energy use were discussed. It was pointed out that decreasing returns are obtained as the level of treatment increases, and it is possible to add more contamination to the environment by increased energy consumption than is removed from the wastewater. Comparisons of energy requirements for a 100 mgd capacity system employing conventional secondary, advanced wastewater treatment and land treatment systems were presented. Energy implications with regard to wastewater reuse were considered, and it was shown that in many instances the reuse of wastewater can conserve energy. The savings are related to the degree of treatment required before reuse. Table 2 is a summary of total energy requirements for various wastewater treatment systems assumed by Hagan and Roberts for direct discharge of the wastewater, employed for various reuse purposes, and the energy requirements for alternative sources of fresh water. Their assumptions include unnecessarily stringent preapplication treatment requirements for the general case of irrigation reuse. Current EPA guidance on the topic is presented in the Results and Discussion section.

Garber et al. (1975) compared biological and physical-chemical processes to treat wastewater in the Los Angeles area. Biological processes were found to be more energy efficient and less stressful on the overall environment. Treatment of the wastewater by physical-chemical methods required almost five times as much energy as activated sludge including nitrification and phosphorus removal. Solids disposal by pumping 90 to 100 miles to the desert to drying beds required 16 times as much energy as the present system of discharging screened digested solids seven miles at sea. Chemical treatment of the sludge followed by mechanical dewatering and disposal at local landfills required 35 times as much energy as the current sludge disposal system.

The general problems associated with small wastewater treatment plants, alternative treatment processes available to small plants, important design considerations, and an economic comparison of the alternatives available were presented by Benjes (1978). Table 3 presents the estimated annual energy required alternative wastewater treatment processes for a range of design flows. Tchobanoglous (1974) conducted a similar analysis and cost factors derived from his work are shown in Table 4.

Jacobs (1977) discussed various ways to more effectively utilize energy at wastewater treatment plants. Use of different types of pumps, sludge dewatering equipment, plant modification and energy recovery from digester gas and incineration of sludge were discussed.

Table 2. Examples of systems to be considered in evaluating energy implications of wastewater reuse (Hagan and Roberts, 1976).<sup>a</sup>

	Total Energy Required for 100 mgd kwh/day
Treatment assumed for discharge	
1. Activated sludge (with chlorination, sludge digestion and landfill disposal)	93,000
2. Biological-chemical (activated sludge with alum treatment, nitrification/denitrification, sludge digestion and landfill disposal)	235,000
3. Tertiary (activated sludge, coagulation/filtration, carbon adsorption, zeolite ion-exchange, recalcination)	1,137,000
Type of reuse	
1. Local irrigation (assume 100-ft head for conveyance)	57,000
2. Distant irrigation (assume 1,500-ft head for conveyance)	615,000
3. Industrial (assume 100-ft head)	57,000
4. Unrestricted (assume 500-ft head)	216,000
Treatment assumed prior to reuse	
For irrigation reuse:	
activated sludge	93,000
biological-chemical	235,000
For industrial reuse:	
biological-chemical	235,000
biological-chemical & desalting	695,000
tertiary	1,137,000
tertiary & desalting	1,597,000
For unrestricted reuse:	
tertiary	1,137,000
tertiary & desalting	1,597,000
Alternative sources of fresh water	
1. Local supplies	57,000
2. Imported	938,000
3. Desalted seawater	6,661,000

<sup>a</sup>Courtesy of Water and Sewage Works, Chicago, Illinois.

Table 3. Estimated energy (electricity and fuel) for alternative treatment processes (Benjes, 1978).

Process <sup>a</sup>	Energy (1000 kwh/yr) Plant capacity (mgd)			
	0.1	0.5	1.0	2.0
Prefabricated extended aeration	139	-	-	-
Prefabricated contact stabilization	95	447	886	-
Custom design, extended aeration	197	857	1,901	-
Oxidation ditch	134	647	1,288	2,571

RBC, nitrification, anaerobic digestion	113	496	1,026	2,005

<sup>a</sup>All with aerated grit chamber, chlorination and sludge drying beds.

A comparison of energy requirements and costs for sludge dewatering equipment is shown in Table 5. Energy requirements and costs for biological treatment systems are presented in Table 6.

Mills and Tchobanoglous (1974) presented detailed methods for calculating the energy consumption by the unit operations and processes used in wastewater treatment. Use of the equations and graphs presented in the paper is illustrated by examples using two alternative flow schemes. Detailed results are presented in tabular form and are easily compared between processes and systems.

Smith (1973) estimated the electrical power consumption by most conventional and advanced processes used to treat municipal wastewater on a unit processes basis. Electrical power consumption for complete plants was estimated by adding the power consumption for the individual processes. A comparison of electrical power consumption by wastewater treatment systems was made with other uses.

Estimates of recoverable energy in digester gases were made by Wesner and Clarke (1978). A discussion of the variation in gas production with the type sludge was presented.

Table 4. Estimated total annual and unit costs for alternative treatment processes with a design flow of 1.0 mgd (Tchobanoglous, 1974).<sup>a</sup>

Process	Initial capital cost dollars <sup>b</sup>	Annual cost, dollars <sup>b</sup>			Unit cost cents/1000 gal <sup>b</sup>

## METHODS AND PROCEDURES

### Equation Development

The graphs presented by Wesner et al. (1978) were converted to lines of best fit at the lower design flow rates (0.1 - 5.0 mgd) and used to calculate the energy requirements for small systems such as those employed at military installations. Least-squares fits of the linear and curvilinear lines were employed. A power function was used to fit the linear lines on the log-log plots and a polynomial equation was used to fit the curvilinear lines. The forms of the two functions are shown below.

$$\log Y = a + b (\log X) + c (\log X)^2 + d (\log X)^3$$

Polynomial function

$$Y = a X^b$$

Power function

Various combinations of the unit operations and processes were selected to form the most commonly used wastewater treatment systems. Energy requirements for each component of the system for various design flow rates were estimated using the equations of best fit. These results were tabulated for easy comparison between various types of treatment systems.

### Design Parameters

Design parameters for all of the unit operations and processes are shown with the energy equations for each operation or process in Appendix A. Additional detail can be obtained by referring to the report by Wesner et al. (1978). The energy relationships for the conventional and advanced wastewater treatment processes are unmodified, but it was necessary to modify the land application energy relationships to conform to accepted practice in cold regions. The slow rate and overland flow application seasons were modified from five months per year to 250 days per year to more realistically reflect actual practice. Rapid infiltration application seasons extend over 365 days per year and not five months per year as shown in the Wesner et al. (1978) report.

### Wastewater Characteristics

Raw wastewater and sludge characteristics used to develop the energy relationships are presented in Appendixes B and C, respectively.

### Energy Recovery

The potential energy available in digester gas was estimated using a figure of 6.5 million Btu/million gallons of wastewater treated. This value is based upon a mixture of primary and waste activated sludge, and the value will vary with the type of sludge and must be adjusted when better data are available. However, a value of 6.5 million Btu/million gallons of wastewater is satisfactory for estimating purposes and will yield a conservative estimate for net energy consumption.

Btu available in digester gas can be converted to electricity, and a conversion factor of 11,400 Btu per kwh can be used to estimate the electricity generated. The conversion factor assumes an electrical generation efficiency of 30 percent. The gas utilization system also requires energy and this must be considered when comparing systems.

### Secondary Energy

Secondary energy requirements are the amounts of energy needed to produce consumable materials used in a wastewater treatment system. Disinfectants, coagulants, sludge conditioning chemicals and regeneration of activated carbon and ion exchange resins require energy in their production, and this energy must be considered when comparing the energy efficiency of various systems.

Methods of construction, materials of construction, seasonal variations and other factors also influence the energy budget for a treatment system, but to a lesser degree than the primary factors such as direct energy consumption on a daily basis. Only the direct energy consumption and the secondary energy requirements are considered in this report.

## RESULTS AND DISCUSSION

### Energy Equations

The equations of the lines of best fit for the energy requirements of the unit operations and processes used in wastewater treatment based on the graphs reported by Wesner et al. (1978) are presented in Appendix A. Design conditions and assumptions used in developing the graphs are presented along with each equation. Details about the conditions imposed upon the equations can be obtained from the Wesner et al. (1978) report. Each equation is cross referenced to the Wesner et al. report. The equation number used in Appendix A coincides with the figure number in the Wesner et al. report; i.e., Equation 3-15 corresponds to Figure 3-15. Only the portions of the curves below a flow rate of 5 mgd were used to determine the line of best fit. This was done to obtain a better trend at the lower flow rates of interest rather than introduce the influence of the higher flow rates. All equations for the linear lines have a correlation coefficient of 0.999 or better.

### Treatment Systems

Flow diagrams of the wastewater treatment systems commonly employed are shown in Figures 2 through 12. The flow diagrams for land applications systems were selected utilizing the preapplication treatment guidelines shown in Table 7. The biological and physical treatment systems shown in Figures 2, 3, 4, 7, 8, 9, 10, and 11 are most often employed in small systems; however, the activated sludge process with sludge incineration (Figure 5), physical-chemical treatment (Figure 6), and the advanced treatment following secondary treatment (Figure 12) have been employed in special cases. These 11 systems can be modified by adding various processes in the treatment train to produce almost any quality effluent desired. Also, a very wide range of energy consumption can be experienced with these basic systems and their modifications.

The raw wastewater characteristics and the expected effluent quality from each of the systems are shown on the figures. The raw water characteristics are also summarized in Appendix B. Sludge characteristics used to develop the energy relationships in Wesner et al. (1978) and this report are presented in Appendix C.

### Energy Consumption

Energy requirements for the components of the treatment systems shown in Figures 2 through 12 for various flow rates of wastewater treated by the systems are presented in Tables 8 through 19. The table

---

I. Slow-rate systems (reference sources include Water Quality Criteria 1972, EPA-R3-73-003, Water Quality Criteria EPA 1976, and various state guidelines).
A. Primary treatment - acceptable for isolated locations with restricted public access and when limited to crops not for direct human consumption.
B. Biological treatment by lagoons or inplant processes plus control of fecal coliform count to less than 1,000 MPN/100 ml <sup>a</sup> acceptable for controlled agricultural irrigation except for human food crops to be eaten raw.
C. Biological treatment by lagoons or inplant processes with additional BOD or SS control as needed for aesthetics plus disinfection to log mean of 200/100 ml (EPA fecal coliform criteria for bathing waters) - acceptable for application in public access areas such as parks and golf courses.
II. Rapid-infiltration systems
A. Primary treatment - acceptable for isolated locations with restricted public access.
B. Biological treatment by lagoons or inplant processes - acceptable for urban locations with controlled public access.
III. Overland-flow systems
A. Screening or comminution - acceptable for isolated sites with no public access.
B. Screening or comminution plus aeration to control odors during storage or application - acceptable for urban locations with no public access.

---

<sup>a</sup>Most probable number of coliform bacteria per 100 ml of sample.

number corresponds to the figure number; i.e., Table 8 is a listing of the energy requirements for a trickling filter treatment system with anaerobic digestion (Figure 2). The last column in each table lists the equations used to calculate the values (Appendix A).

Table 20 shows the energy requirements for components frequently appended to secondary treatment systems to produce a better quality effluent. By modifying the basic systems shown in Figures 2 through 12, it is possible to develop the energy requirements for almost any

system applicable to the treatment of small flows of wastewater. For combinations not shown in the tables, energy requirements can be calculated using the equations in Appendix A.

#### Carbon and Ion Exchange Regeneration

Energy requirements for the regeneration of carbon and ion exchange materials for very low flow systems (0.05 - 0.1 mgd) are shown in Tables 12, 19, and 20 only for comparative purposes. In most cases activated carbon would be replaced rather than regenerated and the energy requirements would be reduced accordingly. The regeneration of ion exchange resins would probably be justified, but depending upon local conditions it may be less expensive to replace ion exchange resins on a fixed schedule rather than to regenerate them.

Energy requirements for carbon regeneration represent greater than 10 percent of the electricity and 93 percent of the fuel consumed in the components of an advanced treatment system following secondary treatment at a flow rate of 5 mgd. At a flow rate of 0.05 mgd, the energy requirements for carbon regeneration have been reduced to 5 percent of the electricity and 57 percent of the fuel requirements. However, the inconvenience of operating additional equipment and the need for highly skilled operation would probably rule out the use of carbon regeneration at very small (< 0.5 mgd) wastewater treatment systems.

#### Gas Utilization

Although the energy required and produced by gas utilization is presented in the examples summarized in Tables 8, 9, and 10, gas utilization in small flow systems, particularly at the lower flow rates of less than 0.5 mgd, may not be advisable. The increased operating expense caused by the need for a more skilled operator and more sophisticated equipment will likely offset any savings from gas utilization. However, this is a decision that must be made on an individual basis.

#### Effluent Quality and Energy Requirements

Table 21 shows the expected effluent quality and the energy requirements for various combinations of the operations and processes shown in Figures 2 through 12 and Tables 8 through 20. Energy requirements and effluent quality are not directly related. Utilizing facultative lagoons and land application techniques, it is possible to obtain an excellent quality effluent and expend small quantities of energy. Although one system may be more energy efficient, the selection of a wastewater treatment facility must be based upon a complete economic analysis. However, with rising energy costs, energy requirements are assuming a greater proportion of the annual cost of operating a wastewater treatment facility, and it is likely that energy costs will

become the predominant factor in the selection of small flow treatment systems. Operation and maintenance requirements, and consequently costs, are frequently kept to a minimum at small installations because of the limited resources and operator skills normally available. This favors the selection of systems employing units with low energy requirements. It is very likely that all future wastewater treatment systems at small installations in isolated areas will be designed employing low energy consuming units and simple operation and maintenance. The only exceptions to this will be in areas with limited space or construction materials, or where surplus energy is available.

The effluent quality expected with each of the treatment systems and the energy requirements shown in Table 21 are presented in the order of decreasing BOD<sub>5</sub> concentration in the effluent. The other parameters (suspended solids, Total P, and Total N) do not necessarily decrease in the same manner because most treatment facilities are designed to remove BOD<sub>5</sub>, but in general there is a trend in overall improvement in effluent quality as one reads down the table. As shown in Table 21, there are many systems available to produce an effluent that will satisfy EPA secondary or advanced effluent standards; however, energy requirements for the various systems are varied and can differ by a factor of greater than 10 to produce the same quality effluent.

For purposes of comparison the total energy (electricity plus fuel) for a typical 1 mgd system has been extracted from Table 21 and listed in Table 22 in order of increasing energy requirements. It is quite apparent from Table 22 that increasing energy expenditures do not necessarily produce increasing water quality benefits. The four systems at the top of the list, requiring the least energy, produce effluents comparable to the bottom four that require the most. Three of the top four are land treatment systems, and their adoption will depend on local site conditions. The facultative pond followed by intermittent sand filter and surface discharge to receiving waters is less constrained by local soil and groundwater conditions.

#### Conventional Versus Land Treatment

A comparison of the energy requirements for a conventional wastewater treatment system consisting of a trickling filter system followed by nitrogen removal, granular media filtration and disinfection with a facultative pond followed by overland flow and disinfection is shown in Figure 13. This comparison is made because of the approximately equivalent quality effluents produced by the two systems (Table 21). The relationships in Figure 13 clearly show that there are significant electricity and fuel savings with the land application system. Similar comparisons for modifications of the two systems can be made by referring to Tables 8, 17, and 20 and selecting combinations to produce equivalent effluents.

Figure 14 shows a comparison of the energy requirements for an activated sludge plant producing a nitrified effluent, followed by

Figure 13. Comparison of energy requirements for trickling filter effluent treated for nitrogen removal and filtered versus facultative pond effluent followed by overland flow treatment.

Figure 14. Comparison of energy requirements for activated sludge, nitrification, filtration and disinfection versus facultative pond effluent followed by rapid infiltration and primary treatment followed by rapid infiltration.

Table 22. Total annual energy for typical 1 mgd system (electrical plus fuel, expressed as 1000 kwh/yr).

Treatment system	Effluent quality				Energy 1000 kwh/yr
	BOD	SS	P	N	
Rapid infiltration (facultative pond)	5	1	2	10	159

granular media filtration and disinfection; a facultative pond followed by rapid infiltration land treatment, and primary treatment followed by rapid infiltration land treatment. The facultative pond system followed by rapid infiltration land treatment is the most energy-efficient wastewater treatment system, but it is closely followed in energy efficiency by the primary treatment and rapid infiltration system. The energy requirements for both of the rapid infiltration land treatment alternatives are less than 10 percent of the energy required for the activated sludge system.

In Figure 15, energy requirements for slow rate land application systems using ridge and furrow and center pivot systems to distribute facultative pond effluent are compared with the energy requirements for an activated sludge plant practicing nitrogen and phosphorus removal, granular media filtration of the effluent, and disinfection prior to discharge. Both the activated sludge and advanced treatment system and the facultative pond and slow rate systems produce approximately equivalent quality effluents. The ridge and furrow flooding technique of land treatment requires less than 10 percent of the energy required by the advanced treatment scheme. Utilizing a center pivot mechanism to distribute the facultative pond effluent increases the energy requirements by a

Figure 15. Comparison of energy requirements for secondary treatment followed by advanced treatment versus facultative pond effluent followed by slow rate land treatment.

factor of five compared with the ridge and furrow flooding technique, but the energy requirements for the center pivot system are less than one-half the energy requirements for the advanced treatment system.

In an energy conscious environment, the land application techniques of treating wastewater have a distinct advantage over the more conventional wastewater treatment systems. When land is available at a reasonable cost, the lower energy requirements for land application systems will likely result in a more cost effective as well as more energy effective system of wastewater treatment.

Figure 15. Comparison of energy requirements for secondary treatment. The graph shows energy requirements for various wastewater treatment methods. The Y-axis represents Energy Requirements in Kilowatt-Hours per Million Gallons (kWh/MGD), ranging from 0 to 2000. The X-axis represents Flow Rate in Million Gallons per Day (MGD), ranging from 0 to 6. The methods compared are: Advanced Oxidation, Reverse Osmosis, Distillation, Electrolysis, Slow Rate Land Treatment, Land Application, Ridge & Furrow Flooding, Ridge & Furrow, and Center Pivot. The land application techniques (Ridge & Furrow Flooding, Ridge & Furrow, and Center Pivot) show the lowest energy requirements, while Advanced Oxidation and Reverse Osmosis show the highest.

## CONCLUSIONS

Based upon the results of the analyses presented in this report, the following conclusions are made.

1. With increasing energy costs, energy consumption is assuming a greater proportion of the annual cost of operating wastewater treatment facilities of all sizes, and because of this trend, it is likely that energy costs will become the predominant factor in the selection of cost-effective small-flow wastewater treatment systems.
2. Small-flow wastewater treatment systems are frequently designed to minimize operation and maintenance, and as energy costs increase, design engineers will tend to select low-energy-consuming systems.
3. Low-energy consuming wastewater treatment systems are generally easier to operate and maintain than energy intensive systems, making the low-energy-consuming systems even more attractive because of the desire to minimize highly skilled operation at small facilities.
4. Where suitable land and groundwater conditions exist, a facultative pond followed by rapid infiltration is the most energy-efficient system described in this report.
5. When surface discharge is necessary and impermeable soils exist, a facultative pond followed by overland flow is the second most energy-efficient system described in this report.
6. Facultative ponds, followed by slow or intermittent sand filters, are the third most energy-efficient systems discussed, and are not limited by local soil or groundwater conditions.
7. Physical-chemical advanced secondary treatment systems utilize the most energy of the conventional methods of producing an effluent meeting the federal secondary effluent standard of 30 mg/l of BOD<sub>5</sub> and suspended solids.
8. Slow rate land application systems following facultative ponds are more energy efficient than most forms of mechanical secondary treatment systems, while also providing benefits of nutrient removal, recovery and reuse.
9. Advanced physical-chemical treatment following conventional secondary treatment consumes approximately 13 times as much electrical energy and 26 times as much fuel as slow rate land treatment to produce an equivalent effluent.

10. Land application wastewater treatment systems following storage ponds (aerated or facultative), preliminary treatment (bar screens, comminutors, and grit removal), or primary treatment are by far the most energy-efficient systems capable of producing secondary effluent quality or better.
11. This study did not consider the energy requirements for production of all materials consumed in the treatment process, but it is not believed that inclusion of such factors would significantly change the relative ranking of the systems discussed. Such inclusion would rather make the differences between simple biological processes and mechanical systems even more dramatic.
